

Architecture guardrail tests

These tests enforce structural boundaries between layers.

Scope

Guardrails apply only to domain-backed command entrypoints (e.g. application, practice, review, plan). Infrastructure commands such as config, init, and internal helpers are excluded.

Rules

- Commands must remain thin orchestration only.
- Domain logic must live in `level.domains.<domain>`.
- Filesystem and parsing must not occur in command modules.
- Aggregation and business logic must be implemented in the corresponding domain and called from the command.

Simple presentation formatting (e.g. joining lines for output) is allowed.

Purpose

These tests exist to:

- Prevent architectural drift
- Enforce layering mechanically
- Provide guardrails for AI-generated changes

They are intentionally strict and represent an architectural contract, not a style preference.
